Java & Secure Programming
(Bad Examples found in JDK)

Marc Schönefeld, University of Bamberg

Illegalaccess.org
Marc Schönefeld, Diplom-Wirtschaftsinformatiker

**For Science:** External doctoral student @ Lehrstuhl für praktische Informatik at University of Bamberg, Bavaria, Germany
  - Thesis project: REFACTORYING OF SECURITY ANTIPATTERNS IN DISTRIBUTED JAVA COMPONENTS

**For Living:** Department for Operational Security Management at computing site for large financial group in Germany
  - Java, J2EE, CORBA [CSMR 2002]
    - design and development
    - Security Hardening (code audit)
The situation

- Java (we cover J2SE here, some aspects also apply to J2EE)
  - is designed as a programming language with inherent security features [Gong, Oaks]
    - JVM-Level: Type Safety, Bytecode integrity checks
    - API-Level: SecurityManager, ClassLoader, CertPath, JAAS
    - Crypto-Support: JCA/JCE, JSSE
  - **So what's the problem?**
Selected Java Security Alerts in 2003/2004:

- Java Runtime Environment May Allow Untrusted Applets to **Escalate Privileges**
- A Vulnerability in JRE May Allow an Untrusted Applet to **Escalate Privileges**
- ...Java Virtual Machine (JVM) May Crash Due to Vulnerability in the Java Media Framework (JMF)...
- ...Java Runtime Environment Remote Denial-of-Service (DoS) Vulnerability ...

Despite of the precautions of the Java Security Architecture, a lot of attack potential ... what’s the cause?
The problem

- A platform (like the Java runtime environment) can only support the programmer’s intent
- What is programmer’s intent? Reflects different perspectives …
  - **Functionality** [application programmer]
    - Java has a large API with lots of predefined functions (sockets, files, …)
  - **Quality** and **ReUse** [middleware programmer]
    - Java provides communication and marshalling on different semantic levels (Sockets, RMI, CORBA, Raw-Serialisation, XML-Serialisation, …)
  - **Safety** [security architect]
    - Java provides Isolation Support, Crypto-Objects and Secure Sockets out of the box
  - **Malicious Intent** [adversary]
    - Undermine security by finding the **weak spots**
    - Java VM and core libraries have (lots of?) **vulnerabilities**
Classloaders and Protection Domains
Why search for security bugs in java code?

- Component based software development
  - 3rd party middleware components (web servers, graphics libraries, PDF renderer, ... ) are all over the place
  - We REUSE many of them in trusted places (bootclassloader)
  - But can we really trust them?

Questions:
- Does my super duper 3rd-party graphics library include vulnerable object implementation that can be triggered by an attacker?
- Is the JDK secure in isolating my confidential XML data from other malicious applets loaded into the same VM?
- Object serialisation is safe, isn’t it?

Sun's Security Code Guidelines (last update Feb 2, 2000!):

1. Careful usage of privileged code
2. Careful handling of Static fields
3. Reduced scope
4. Careful selected public methods and fields
5. Appropriate package protection
6. If possible Use immutable objects
7. Never return a reference to an internal array that contains sensitive data
8. Never store user-supplied arrays directly
9. Careful Serialization
10. Careful use native methods
11. Clear sensitive information

http://java.sun.com/security/seccodeguide.html
Java Security Antipatterns

- Security unaware coding create vulnerability by ignoring the security patterns
- Typical Java Secure Coding Antipatterns:
  - Ignoring Language Characteristics (like Integer Overflow)
  - Careless Serialisation, careless use of privileged code
  - Inappropriate Field and Method Visibility
  - Covert Channels in non-final Static Fields
- They hide in your own code and the libraries you use
- Due to academic interest we audited parts of the Sun JDK 1.4.x and present the findings on the following slides:
How to search for security bugs in java code?

<table>
<thead>
<tr>
<th>Source Code Detectors</th>
<th>PMD, Checkstyle</th>
<th>useful only if source code is available and complete [in most of the cases it isn’t]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Decompilers</td>
<td>JAD (!), JODE</td>
<td>Time consuming analysis, needs experience</td>
</tr>
</tbody>
</table>
| Bytecode audit analyzers | Findbugs (bases on Apache BCEL) | Bytecode detectors (visitor pattern):
  - predefined (software quality)
  - Self-written (for security audit) |
| Policy evaluation tools | jChains ([http://jchains.dev.java.net](http://jchains.dev.java.net)) | Test if program needs specific permissions
  Useful to reverse engineer protection domains |
The following discussion bases on JVM bytecode analysis.

**Findbugs** ([http://findbugs.sourceforge.net](http://findbugs.sourceforge.net))
- Statically Detector for bug patterns in java code
- Developed by the University of Maryland (Puth and Hovemeyer)

Open Source
- based on the BCEL (Apache Bytecode Engineering Library)
- Visitor-pattern analysis of
  - class structure and inheritance
  - control and data flow
- GUI/command line
- **And**: Extensible, **allows to write own detectors**
Java Security Antipatterns

- **Antipatterns** (bugs, flaws) in trusted code (like rt.jar) cause Vulnerabilities
  - **Availability:**
    - AP1: Integer, the Unknown Type (java.util.zip.*)
    - AP2: Serialisation side effects (java.io.*)
  - **Integrity:**
    - AP3: Privileged code side effects (Luring attacks break sandbox)
    - AP4: Inappropriate Scope (Access control violation)
    - AP5: Non-Final Static Variables (Covert channels between applets)
  - **Secrecy:**
    - AP6: Insecure Component Reuse (org.apache.*, Sniff private XML data between applets)

- **Goal:** Define a binary audit toolset to **detect the antipatterns** in your own and the 3rd-party components to be able to **fix the vulnerabilities**
Java Antipattern 1: Integer overflow

- According to blexim (Phrack #60), integer overflows are a serious problem in C/C++, so they are in Java:
  - All Java integers are bounded in the $[-2^{31}, +2^{31}-1]$ range
  - In Java this is true: $-2^{31}=2^{31}+1$
  - Silent Overflow is a problem: Sign changes are not reported to the user, no JVM flag set

- Code of JDK 1.4.1_01 was based on the false assumption that java integers are unbounded, which led to a range of problems in the java.util.zip package
Java Antipattern 1: Integer overflow

The crash is caused by a parameter tuple
(new byte [0], x, Integer.MAX_VALUE - y), where x > y, x, y ≥ 0

 È silent overflow in the trusted JDK routines by fooling the parameter checks, so the overflow is neither detected by the core libraries nor the JVM.

 È The native call updateBytes to access a byte array leads to an illegal memory access. Consequently the JVM crashes.

D:\> java CRCCrash
An unexpected exception has been detected in native code outside the VM.

#
# The exception above was detected in native code outside the VM
#
# Java VM : Java HotSpot(TM ) Client VM (1.4.1_01 -b01 mixed mode)
Java Antipattern 1: Integer overflow

The CRC32 class allows to calculate a checksum over a buffer:
If you have a byte buffer (1,2,3,4) and want to calculate the checksum over it you need to call:
```java
CRC32 c = new java.util.zip.CRC32 ();
c.update (new byte []{1,2,3} ,0 ,3);
```
But if you do the following:
```java
c.update (new byte [0] ,4 ,Integer. MAX_VALUE -3);
```
You will crash the JVM of JDK 1.4.1_01 and some versions of JDK 1.3.1
Java Antipattern 1: Integer overflow, Risk and extent

**Risk:**
If the attacker manages to exploit this function in an environment were multiple users share a single JVM (like a Lotus Domino server or a Tomcat HTTP server) he may cause a denial-of-service condition.

**Extent:**
More trusted functions were found vulnerable:
- `java.util.zip.Adler32().update();`
- `java.util.zip.Deflater().setDictionary();`
- `java.util.zip.CRC32().update();`
- `java.util.zip.Deflater().deflate();`
- `java.util.zip.CheckedOutputStream().write();`
- `java.util.zip.CheckedInputStream().read();`
- `java.text.Bidi.<init> ;`

also bugnr = {4811913, 4812181, 4812006, 4811927, 4811917, 4982415, 4944300, 4827312, 4823885}
### Java Antipattern 1: Integer overflow, the Refactoring

| Before JDK 1.4.1 01 | public void update(byte[] b, int off, int len) {
|                    |     if (b == null) {
|                    |         throw new
|                    |         NullPointerException(); }
|                    |     if (off < 0 || len < 0 || off + len > b.length) {
|                    |         throw new ArrayIndexOutOfBoundsException();
|                    |     }
|                    |     crc = updateBytes(crc, b, off, len);
| After JDK 1.4.1 02 | public void update(byte[] b, int off, int len) {
|                    |     if (b == null) {
|                    |         throw new NullPointerException(); }
|                    |     if (off < 0 || len < 0 || off > b.length - len) {
|                    |         throw new ArrayIndexOutOfBoundsException();
|                    |     }
|                    |     crc = updateBytes(crc, b, off, len); |

**Integer Overflow Bytecode Pattern**

**Bytecode of Refactoring**
Java Antipattern 1: Harmful integer overflow, How to find during auditing?

1. Find candidate methods by detecting `iadd` opcodes
2. Does the `iadd` use user-supplied data (does it use data from the stack supplied by `iload`) to perform a range check
3. Is a native method called afterwards (`invokevirtual`, `invokestatic`), that takes the same data

This process can be implemented by a Findbugs bytecode detector
The JVM does not provide an overflow flag like a normal x86 processor (designed in 1978), so there is no way to detect those conditions during runtime. The JVM in Java 1.5 (aka 5.0 aka Tiger) 27 years later does not improve this shortcoming.

Suggestions for JDK 6.0:
- To avoid burdening the (security unaware) programmer, a bounded primitive integers (like in Ada) is helpful:
  ```java
  subtype Month_Type is Integer range 1..12;
  ```
- If this is all too complex for the java compiler to handle, it could at least list a potential overflow as compiler warning (maybe in Java 6.0?)
Antipattern 2: Serialisation side effects

- The normal way to create a java object is to use the `new` instruction, which calls the constructor of a class.
- But: The Java serialisation API (part of `java.io` package) allows to **bypass constructors** and create new instances of an object type by simply sending them to an `java.io.ObjectInputstream` (OIS), which is bound to a socket, a file or a byte array.
- OIS objects are commonly used by remote communications such as RMI or persistency frameworks to import pre-built objects into the JVM.
- When an object is read from an OIS the most derived `readObject` method of the class is called.
AP 2: Risk and Extent

**Risk**
- Reading serialized objects may force the JVM to branch into complex or vulnerable code regions that are called in the `readObject` method.
- `readObject` methods may linger in your own code, the JDK classes and any 3rd party library you use.
- Attacker may prepare special handcrafted data packets with serialized data.

**Extent**

<table>
<thead>
<tr>
<th>Class</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>java.util.regex.Pattern</code></td>
<td>Triggers complex computation, &quot;JVM may become unresponsive&quot; [Sun Alert 57707]</td>
</tr>
<tr>

<td>Causes JVM crash on Win32</td>
</tr>
<tr>
<td><code>java.util.HashMap</code></td>
<td>Triggers an unexpected OutOfMemoryError which may kill the current listening thread and disable the service (as an error it bypasses most try/catch checks)</td>
</tr>
</tbody>
</table>
AP 2: Risk and Extent

Sun(sm) Alert Notification

- Sun Alert ID: 57707
- Synopsis: Java Runtime Environment Remote Denial-of-Service (DoS) Vulnerability
- Category: Security
- Product: Java SDK and JRE
- BugIDs: 5037001
- Avoidance: Upgrade
- State: Resolved
- Date Released: 20 Dec 2004

1. Impact

A vulnerability in the Java Runtime Environment (JRE) involving object deserialization could be exploited remotely to cause the Java Virtual Machine to become unresponsive, which is a type of Denial-of-Service (DoS). This issue can affect the JRE if an application that runs on it accepts serialized data from an untrusted source.

Sun acknowledges with thanks, Marc Schoenefeld, for bringing this issue to our attention.

2. Contributing Factors
### Before

**JDK 1.4.2 05**

```java
private void readObject(java.io.ObjectInputStream s) throws...
{
    s.defaultReadObject(); // Initialize counts
    groupCount = 1;
    localCount = 0; // Recompile object tree
    if (pattern.length() > 0)
        compile(); // so we compile for the next 1600 years
    else
        root = new Start(lastAccept);
}
```

### After

**JDK 1.4.2 06**

```java
private void readObject(java.io.ObjectInputStream s) throws...
{
    s.defaultReadObject(); // Initialize counts
    groupCount = 1; // if length > 0,
    localCount = 0; // the Pattern is lazily compiled
    compiled = false;
    if (pattern.length() == 0) {
        root = new Start(lastAccept);
        matchRoot = lastAccept;
        compiled = true;
    }
}
```
AP2: How to find during code audit?

1. Find candidate classes by detecting `readObject` definitions.
2. For these classes determine if the control flow branch into harmful code:
   I. Search for algorithmic complexity (does it compile a regex for the next 800 years?)
   II. Search for endless loops (bytecode backward branches)
   III. Does to code call into vulnerable native code and propagates the total or some part of the payload?

This process can be implemented by a `Findbugs` bytecode detector.
AP2: Conclusion and Suggestions

- The `readObject` method is designed primarily for accepting and **checking** `Serializable` data.
- Nested `readObject` invocations occur for nested `Serializable` classes, so the malicious payload does not have to be in the root object.
- Try to defer complex operations from the time of creation to the time of first usage.
- Similar considerations apply for the `readExternal` method which implements the receiving part of the `Externalizable` interface.
AP3: Privileged Code Side Effects

The Basic Java Access Algorithm:

- A request for access is granted if, and only if every protection domain in the current execution context has been granted the said permission, that is, if the code and principals specified by each protection domain are granted the permission.
- A permission is only granted when all protection domain $D_i$ contain the permission $p$.

$$p \in \left\{ \bigcap_{i=1}^{n} D_i \right\}$$
AP3: Privileged Code Side Effects

- Privileged code (*doPrivileged*) is used to break out of the stack inspection algorithm.
- Needed where the permissions on the application level (*user classes*) do not match the needed permissions to perform necessary operations on the middleware/system level (*rt.jar*).
AP3: Privileged Code Side Effects: Risk and Extent

**Risk**
- An attacker may misuse this condition to escalate privileges and escape a limited protection domain (such as the JNLP or applet sandbox)
  - he knows the privileged code blocks in the JDK and the privileged codesources of the application
  - by a luring attack he tries to trick control into privileged code blocks and force that block to use parts of his injected payload

**Extent**

<table>
<thead>
<tr>
<th>java.awt.font.ICC_Profile</th>
<th>escape the applet sandbox and test existence of files on the client’s machine</th>
</tr>
</thead>
<tbody>
<tr>
<td>java.awt.Font (i)</td>
<td>transport temporary files (such as executables) to the client’s machine, which can be launched later (<a href="http://www.derkeiler.com/Mailing-Lists/Full-Disclosure/2004-07/0462.html">http://www.derkeiler.com/Mailing-Lists/Full-Disclosure/2004-07/0462.html</a>)</td>
</tr>
<tr>
<td>Java.awt.Font(ii)</td>
<td>fill up the remaining free space of file system of the client machine with a large file containing zero bytes</td>
</tr>
</tbody>
</table>

...
AP3: Privileged Code Side Effects: Risk and Extent

[Full-Disclosure] IE sucks : sun java virtual machine insecure tmp file creation

---

Introducion

Actually I wasn't really sure if I ought to post this, but after some consideration I decided that it might serve as an example of the completely normal upgrade we find internet explorer is today.

There's a very minor loop with the way the sun java virtual machine creates temporary files from outputs. IE leaves it off the disk, confusing that with some unsolved issues in IE can lead to remote code execution.
No refactorings available

The described bugs are still in the JDK, so unfortunately no refactorings available

Although most of those were reported to Sun in Q2/2004 or earlier
AP3: Privileged Code Side Effects: How to audit?

1. find candidate classes by detecting \texttt{doPrivileged} calls
2. For these classes determine if user-supplied data is propagated to the privileged code block that causes to
   I. Pass access to protected resources
   II. leak secret data
   III. Perform unwanted modifications to untrusted code

This process can be partially implemented by a \texttt{Findbugs} bytecode detector
AP3: Conclusion and Suggestions

**Conclusion**

- *doPrivileged* is a **powerful** but **dangerous** construct to tweak protection domains

**Suggestion**

**To Sun:**

- Please fix bugs in privileged code JDK blocks

**To Component Users:**

- Check 3rd party libraries for vulnerable *doPrivileged* blocks before usage, as they may break your security policy

**To Middleware Developers:**

- Keep privileged code in own code as short as possible
  

- Detaint user-supplied data before propagating it to privileged code
AP4: Inappropriate Scope

- As a rule, **reduce the scope** of methods and fields **as much as possible**. Check whether package-private members could be made private, whether protected members could be made package-private/private, etc.  [Sun Security Code Guidelines]

- This should be especially true when you design trusted JDK extensions, such as the Java Media Framework (JMF)
Risk

An attacker can exploit the trusted protection domain “AllPermissions” of a java extension in `jre/lib/ext` to escalate privileges. For example the JMF

- installs extra trusted classes to `jre/lib/ext`
- accesses system memory via native routines
- The public JMF class `com.sun.media.NBA` exposes a public pointer to physical memory [long value data]
- So untrusted applets may read your system memory
1. Impact

A vulnerability in the Java(TM) Media Framework (JMF) may potentially allow an untrusted applet to exit unexpectedly ("crash") the Java Virtual Machine (JVM) or gain unauthorized privileges.
### AP4: Inappropriate Scope: Refactoring

<table>
<thead>
<tr>
<th>Before (JMF 2.1.1c)</th>
<th>After (JMF 2.1.1e)</th>
</tr>
</thead>
<tbody>
<tr>
<td>public class NBA {</td>
<td>public final class NBA {</td>
</tr>
<tr>
<td>public void finalize()</td>
<td>protected final synchronized void finalize()</td>
</tr>
<tr>
<td>public Object getData()</td>
<td>public synchronized Object getData()</td>
</tr>
<tr>
<td>public Object clone()</td>
<td>public synchronized Object clone()</td>
</tr>
<tr>
<td>public void copyTo(NBA nba)</td>
<td>public synchronized void copyTo(NBA nba)</td>
</tr>
<tr>
<td>public void copyTo(byte javadata[])</td>
<td>public synchronized void copyTo(byte javadata[])</td>
</tr>
<tr>
<td>public long data;</td>
<td>private long data;</td>
</tr>
<tr>
<td>public int size;</td>
<td>private int size;</td>
</tr>
<tr>
<td>public Class type;</td>
<td>private Class type;</td>
</tr>
<tr>
<td>}</td>
<td>}</td>
</tr>
</tbody>
</table>

1) Creation of subclasses is forbidden, to prevent leaking of secret data by new methods
2) Scope of public finalize method degraded to protected, so no class can overwrite it
3) Data fields were moved to appropriate private (class local) scope
AP4: Inappropriate Scope Side Effects: How to audit?

1. find candidate classes by detecting public classes
2. For these classes determine if
   I. Data fields are declared as public
   II. Methods are declared as public
   III. Internal references to private, protected data are returned by a public method

The candidate selection can be implemented by using the predefined detectors of Findbugs
Conclusion

Inappropriate scope on fields and methods may allow to bypass access control mechanisms.

Suggestion

Refrain from using public variables. Instead, let the interface to your variables be through accessor methods. In this way it is possible to add centralized security checks, if required.

Make sure that any public method that has access to and/or modifies any sensitive internal states includes a security check.
AP5: Non-Final Static Fields

- "Refrain from using non-final public static variables"
  - To the extent possible, refrain from using non-final public static variables because there is no way to check whether the code that changes such variables has appropriate permissions.
  - In general, be careful with any mutable static states that can cause unintended interactions between supposedly independent subsystems"

[Sun Security Code Guidelines]
  - the term covert channel has the following definition:
    - A communication channel that is not normally intended for data communication. It allows a process to transfer information indirectly in a manner that violates the intent of the security policy.

We will show that the Antipattern careless use of Static Variables allows malicious code to exploit covert channels between protection domains
AP5: Non-Final Static Variables, Risk & Extent

**Risk**
- Static Variables that are loaded by the boot classloader (like the ones in `rt.jar`) or by the extension classloader are singleton objects in a JVM
- **Non-final static String fields may transport**

![Diagram showing the flow of serialized objects between domains](chart.png)

- **Browser VM**
- **Applet from site A**
  - Serial obj.
- **Protection Domain A**
- **Applet from site B**
  - Serial obj.
- **Protection Domain B**
- **Protection Domain /lib/rt.jar „AllPermissions“**
- org.apache.xalan.processor.XSLProcessorVersion.LANGUAGE
- org.apache.xalan.processor.XSLProcessorVersion.S_VERSION
- javax.swing.JDesktopPane.LIVE_DRAG_MODE
- ...

---

**Non-final static String fields may transport**

These non-final static String fields are shared across different protection domains, which can lead to security vulnerabilities if not handled properly.
Unsigned Java-Applets jump out of Sandbox
The **final** modifier prohibits modification of a variable after initial value was set. Initially they only used it to protect their product name.
AP5: Non-Final Static Variables: How to audit?

1. Via a built-in **findbugs** detector find candidate classes by searching for **public** classes

2. For these classes find
   I. Primitive Data fields and Strings are declared as **public static**, non-final
   II. Object Type Data fields, Arrays and Containers are declared as **public static**
   III. Methods that allow access on non-public instances of (I + II)
**AP5: Conclusion and Suggestions**

**Conclusion**
- Non-final static final fields allow to establish covert channels between protection domains and bypass restrictions such as the applet sandbox.

**Suggestion**
- To the extent possible, refrain from using non-final public static variables because there is no way to check whether the code that changes such variables has appropriate permissions.
- In general, be careful with any mutable static states that can cause unintended interactions between supposedly independent subsystems.
Antipattern 6: Insecure component reuse

- Distributed component-structured applications can consist of software components which are supplied by different vendors. Therefore one has to distinguish between application owners and software component vendors and there is a needs for corresponding protection: [Hermann, Krumm]
- 3rd – party components might be built with a functionality based programmer intend, whereas the control of the confined execution models of the JDK require a security based programmer intend.
- JDK as a component-structured middleware application uses a lot of XML functionality from the Apache foundation. Is there enough protection against vulnerabilities of these 3rd-party components embedded in JDK?
AP6: Insecure component reuse, Risk & Extent

**Risk**

- The XSLT parser embedded in JDK is directly taken from a previous apache XALAN standalone version, downloadable from [http://xml.apache.org](http://xml.apache.org)
- It is highly configurable, especially it allows to customize the functions that may be employed during XSLT (extensible stylesheet language transformations)
- Non-final static arrays in trusted libraries may contain objects that are allowed to process data throughout the entire JVM
- We will show that the Antipattern **insecure component reuse** allows malicious code to exploit visibilities granted to trusted code by inserting malicious callbacks
1. Impact  The XSLT processor included with the Java Runtime Environment (JRE) may allow an untrusted applet to read data from another applet that is processed using the XSLT processor and may allow the untrusted applet to escalate privileges.

Sun acknowledges, with thanks, Marc Schoenefeld for bringing these issues to our attention.
This refactoring is **adjusting** the enhanced functionality of the component to the level needed **for running the component securely** in confined execution models. Technically the refactoring cures an antipattern 4 and an antipattern 5.

The **private** modifier prohibits malicious code to modify the table consisting the built-in functions of the XSLT parser.
AP6: Insecure component reuse: How to audit?

1. 3rd-party components may include all types of antipatterns, from our experience check at least for the antipatterns presented here
   1. Check for Integer Overflow
   2. Check for proper Serialisation, watch for side effects
   3. Check for defensive use of privileged code, especially when using privileged or “AllPermission” protection domains
   4. Adjust inappropriate scope to the level needed and add security checks to public available fields and functionality
   5. Close covert channels in static non-final fields and static mutable container types (also indirect uses)
**Conclusion**

- Even if your own code is secure, 3rd-party components may ruin your security concept.

**Suggestion**

- Ask the vendor of the components you reuse, whether they check their components with findbugs or similar tools.
- Ask for a findbugs report before buying, this may increase your trust to component.
- A lot of open source projects already include such a report, but some closed source guys still have to learn.
